## BUFFER PROBLEMS (EXAMPLES WITH SOLUTIONS)

Except in the problems specifically dealing with corrections for activity coefficients, these problems have been solved by using concentrations as if they were activities. The resulting answers are therefore approximate. For many cases, however, the use of activity coefficients is not required for the preparation of biological buffers.

## Example 1: Predominant Species of a Buffer Substance as a Function of pH

The relationship shown above indicates the predominant species in solution. Remember that the successive $\mathrm{pK}_{\mathrm{a}}$ values of a buffer are related to the successive proton dissociation reactions. Thus, when the pH of the solution has a value equal to a particular $\mathrm{pK}_{\mathrm{a}}$, the two species of the buffer participating in the dissociation described by that $\mathrm{pK}_{\mathrm{a}}$ are present in equal concentrations (e.g., $\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{1-}\right]=\left[\mathrm{HPO}_{4}^{2-}\right]$ at pH 7.20 ). These are the predominant species when the solution pH is near to this particular value. The boundaries of each region are the half-way points between values corresponding to "neighboring" pK 's.

## 1. What are the predominant species of citrate at $\mathbf{p H} 5.25$ ?

Since citric acid is a tricarboxylic acid (see the Table of Common Biological Buffers), it has three $\mathrm{pK}_{\mathrm{a}}$ values. These values are $3.13\left(\mathrm{pK}_{1}\right), 4.76\left(\mathrm{pK}_{2}\right)$, and $6.40\left(\mathrm{pK}_{3}\right)$. The half-way point between the values for $\mathrm{pK}_{2}$ and $\mathrm{pK}_{3}$ is 5.58. Thus, the stated value $\mathrm{pH}=5.25$ is closer to $\mathrm{pK}_{2}$ than to $\mathrm{pK}_{3}$. Accordingly, the predominant species in solution are those represented by the equilibrium of $\mathrm{pK}_{2}$, namely $\mathrm{H}_{2} \mathrm{Cit}^{1-}$ and $\mathrm{HCit}^{1-}$.

## Examples 2-4: Calculating the Composition of a Buffer

2. What is the composition of 0.1 M sodium acetate buffer, $\mathbf{p H} 5.00$ ?

From the Table of Common Biochemical Buffers, acetic acid ( $\mathrm{HAc}, \mathrm{Ac}^{-}$) has a $\mathrm{pK}_{\mathrm{a}}$ of 4.76. Solving the Henderson-Hasselbalch equation

$$
\begin{aligned}
& \mathrm{pH}=\mathrm{pK}_{\mathrm{a}}^{\prime}+\log \frac{\mathrm{cB}}{\mathrm{c} \mathrm{HB}} . \\
& 5.00=4.76+\log \frac{\mathrm{Ac}^{1-}}{\mathrm{HAc}}
\end{aligned}
$$

Rearranging gives

$$
\begin{gathered}
\log \frac{\mathrm{Ac}^{1-}}{\mathrm{HAc}}=5.00-4.76=0.24, \text { or } \\
\frac{\mathrm{Ac}^{1-}}{\mathrm{HAc}}=1.74
\end{gathered}
$$

$$
\mathrm{Ac}^{1-}=1.74 \mathrm{HAc}
$$

Substituting into the equation of total buffer concentration $\left(\mathrm{HAc}+\mathrm{Ac}^{1-}=0.1\right)$

$$
\begin{gathered}
\mathrm{HAc}+1.74 \mathrm{HAc}=0.1 \\
\mathrm{HAc}=0.036 \mathrm{M} \\
\mathrm{Ac}^{1-}=1.74 \quad 0.036==0.064 \mathrm{M}
\end{gathered}
$$

From the equation of ionic balance

$$
\mathrm{Na}^{+}=\mathrm{Ac}^{1-}=0.064 \mathrm{M}
$$

So, in the specified buffer, the concentration of acetic acid (HAc) is 0.036 M , while the concentrations of acetate ion $\left(\mathrm{Ac}^{1-}\right)$ and sodium ion $\left(\mathrm{Na}^{+}\right)$are 0.064 M .
3. Write directions for making 1 L of the buffer described in example 2 , using method $A$. What volume of the sodium hydroxide solution will be required?

Prepare 500 mL of 0.2 M HAc . Prepare 100 mL of 1.0 M NaOH . Dilute the HAc to 900 mL . Add NaOH to pH 4.95 . Adjust to final volume and pH .

From example 2, 0.064 mol of $\mathrm{Ac}^{1-}$ must be produced. This corresponds to the addition of 0.064 mol of NaOH . Since the NaOH solution is $1.0 \mathrm{M}, 0.064 \mathrm{~L}$ or 64 mL will be required.
4. What is the composition of 0.05 M potassium phthalate buffer, pH 5.00 ? Phthalic acid ( $\mathbf{P H}_{2}, \mathbf{P H}^{1-}, \mathbf{P}^{2-}$ ) is dibasic with $\mathrm{pK}_{\mathrm{a}}$ values of 2.95 and 5.41.

All three species of the buffer will be present, so two Henderson-Hasselbalch relationships are required to describe the solution equilibria:

$$
\begin{aligned}
& \text { for } \mathrm{pK}_{1}, 5.00=2.95+\log \frac{\mathrm{PH}^{1-}}{\mathrm{PH}_{2}} \\
& \text { for } \mathrm{pK}_{2}, 5.00=5.41+\log \frac{\mathrm{P}^{2-}}{\mathrm{PH}^{1-}} .
\end{aligned}
$$

Solving these equations separately gives

$$
\begin{array}{ccc}
\mathrm{PH}_{2}=9 \times 10^{-3} \mathrm{PH}^{1-} & \text { or } & \mathrm{PH}^{1-}=112 \mathrm{PH}_{2} \\
\mathrm{PH}^{1-}=2.57 \mathrm{P}^{2-} & \text { or } & \mathrm{P}^{2-}=0.390 \mathrm{PH}^{1-}
\end{array}
$$

Substituting into the equation for total buffer concentration $\left(\mathrm{PH}_{2}+\mathrm{PH}^{1-}+\mathrm{P}^{2-}=0.05\right)$ and solving for $\mathrm{PH}^{1-}$ gives

$$
\begin{gathered}
9 \times 10^{-3} \mathrm{PH}^{1-}+\mathrm{PH}^{1-}+0.390 \mathrm{PH}^{1-}=0.05 \\
\mathrm{PH}^{1-}=0.036 \mathrm{M}
\end{gathered}
$$

Back substituting into the expressions obtained from the individual Henderson-Hasselbalch equations

$$
\begin{gathered}
\mathrm{PH}_{2}=9 \times 10^{-3} \mathrm{PH}^{1-}=3.22 \times 10^{-4} \mathrm{M} \\
\mathrm{P}^{2-}=0.390 \mathrm{PH}^{1-}=0.014 \mathrm{M}
\end{gathered}
$$

As a check to your calculations, the total buffer concentration is

$$
\mathrm{PH}_{2}+\mathrm{PH}^{1-}+\mathrm{P}^{2-}=3.22 \times 10^{-4}+0.036+0.014=0.05 \mathrm{M}
$$

From the equation for ionic balance, the total $\mathrm{K}^{+}$concentration is

$$
\mathrm{K}^{+}=\mathrm{PH}^{1-}+2 \mathrm{P}^{2-}=0.064 \mathrm{M}
$$

## Examples 5 and 6: Buffer Capacity

5. How much acid can be generated in a 10 mL reaction mixture, buffered at $\mathbf{p H} 5.50$ with pyridine-chloride, $\mathrm{c}_{\mathrm{t}}=0.1 \mathrm{M}$, if the maximum allowable decrease in pH cannot be greater than 0.1 unit?

Pyridine $\left(\mathrm{P}, \mathrm{PH}^{+}\right)$is a monoacidic base with $\mathrm{pK}_{\mathrm{a}}=5.23$. To obtain the buffer composition at pH 5.50 , solve the Henderson-Hasselbalch equation and the total buffer concentration equations as described above

$$
5.50=5.23+\log \frac{\mathrm{P}}{\mathrm{PH}^{+}}
$$

$$
\mathrm{P}+\mathrm{PH}^{+}=0.1
$$

$$
\mathrm{P}=0.065 \mathrm{M} \quad \text { and } \quad \mathrm{PH}^{+}=0.035 \mathrm{M}
$$

At pH 5.40 (the maximal allowable decrease), the composition is similarly given by

$$
\begin{gathered}
5.40=5.23+\log \frac{\mathrm{P}}{\mathrm{PH}^{+}} \\
\mathrm{P}+\mathrm{PH}^{+}=0.1 \\
\mathrm{P}=0.060 \mathrm{M} \quad \text { or } \quad \mathrm{PH}^{+}=0.040 \mathrm{M}
\end{gathered}
$$

The increase in $\mathrm{PH}^{+}$is is equal to the mmoles of acid generated in the reaction. In 10 mL , this change in pH corresponds a change in concentration of

$$
0.040-0.035=0.005 \mathrm{M}
$$

$$
0.010 \mathrm{~L} \times 0.005 \mathrm{M}=5 \times 10^{-5} \text { moles }=0.050 \text { mmoles }
$$

Thus, up to 0.050 mmoles of acid can be formed before the pH change will exceed the set limit.
6. If you use PIPES ( $\mathrm{PH}^{-}, \mathrm{P}^{2-}$ ) at $\mathbf{p H} 7.00$, if you expect 0.25 mmoles of base $\left(\mathrm{OH}^{-}\right)$ to be formed in a 50 mL reaction mixture, and if you want $\Delta \mathrm{pH}$ to be no greater than 0.05 , what must the total buffer concentration be?

The buffer equilibrium at the pH of interest is

$$
\operatorname{PIPES} \cdot \mathrm{H}^{-}\left(\mathrm{PH}^{-}\right) \leftrightarrow \operatorname{PIPES}^{-}\left(\mathrm{P}^{2-}\right)\left(\mathrm{pK}_{4}=6.80\right)
$$

Let the subscripts i and f stand for "initial" and "final," respectively. Initially

$$
7.00=6.80+\log \frac{\mathrm{P}_{\mathrm{i}}^{2-}}{\mathrm{PH}_{\mathrm{i}}^{-}}, \quad \Rightarrow \quad \frac{\mathrm{P}_{\mathrm{i}}^{2-}}{\mathrm{PH}_{\mathrm{i}}^{-}}=1.58
$$

After the reaction is complete

$$
7.05=6.80+\log \frac{\mathrm{P}_{\mathrm{f}}^{2-}}{\mathrm{PH}_{\mathrm{f}}^{-}}, \quad \Rightarrow \quad \frac{\mathrm{P}_{\mathrm{f}}^{2-}}{\mathrm{PH}_{\mathrm{f}}^{-}}=1.78
$$

The $\mathrm{OH}^{-}$will convert $\mathrm{PH}^{-}$to $\mathrm{P}^{2-}$. Since 0.25 mmoles of $\mathrm{OH}^{-}$in 50 mL is $0.005 \mathrm{mmole} / \mathrm{mL}$, the $\Delta \mathrm{P}^{2-}$ will be 0.005 M . Likewise, the $\Delta \mathrm{PH}^{1-}$ will be -0.005 M .

$$
\mathrm{P}_{\mathrm{f}}^{2-}=\mathrm{P}_{\mathrm{i}}^{2-}+0.005 ; \quad \quad \mathrm{PH}_{\mathrm{f}}^{1-}=\mathrm{PH}_{\mathrm{i}}^{1-}-0.005
$$

From the above equations

$$
\begin{gathered}
\mathrm{P}_{\mathrm{i}}^{2-}=1.58 \mathrm{PH}_{\mathrm{i}}^{1-} \\
\mathrm{P}_{\mathrm{i}}^{2-}+0.005=\mathrm{P}_{\mathrm{f}}^{2-}=1.78 \mathrm{PH}_{\mathrm{f}}^{1-}=1.58\left(\mathrm{PH}_{\mathrm{i}}^{1-}-0.005\right)
\end{gathered}
$$

Solving these two equations simultaneously:

$$
\mathrm{PH}_{\mathrm{i}}^{1-}=0.070 \mathrm{M} ; \quad \mathrm{P}_{\mathrm{i}}^{2-}=0.11
$$

Now

$$
\begin{aligned}
& c_{t}=\mathrm{PH}^{-}+\mathrm{P}^{2-} \\
& \mathrm{c}_{\mathrm{t}}=0.07+0.11=0.18
\end{aligned}
$$

The total buffer concentration required is 0.18 M .

## Example 7: Buffer Composition With Desired Ionic Strength

7. Calculate the composition of a glycinamide-chloride ( $\mathbf{G H}^{+}$, G) buffer of $\mathbf{p H} 8.00$, ionic strength 0.05 .

The ionic balance equation, the equation for ionic strength, and the Henderson-Hasselbalch equation, respectively, give the following

$$
\begin{gathered}
\mathrm{Cl}^{-}=\mathrm{GH}^{+}=0.05 \\
\mathrm{I}=\frac{1}{2}\left(\mathrm{GH}^{+} \times 1+\mathrm{Cl}^{-} \times 1\right)=0.05 \\
8.00=8.20+\log \frac{\mathrm{G}}{\mathrm{GH}^{+}}
\end{gathered}
$$

Substituting the value for $\mathrm{GH}^{+}$into the Henderson-Hasselbalch equation and solving for G gives

$$
\begin{array}{cl}
\mathrm{GH}^{+}=0.05 \mathrm{M} & \mathrm{G}=0.032 \mathrm{M} \\
\mathrm{c}_{\mathrm{t}}=\mathrm{GH}^{+}+\mathrm{G}=0.082 \mathrm{M} & \mathrm{Cl}^{-}=0.05 \mathrm{M}
\end{array}
$$

## Example 8: Buffer Composition With Desired Osmolarity

8. Calculate the composition of a potassium phthalate buffer ( $\mathbf{P H}_{2}, \mathrm{PH}^{\mathbf{1}-}, \mathrm{P}^{\mathbf{2}-}$ ) of $\mathbf{p H}$ 5.75 and osmolarity 0.134 .

Although phthalic acid has two $\mathrm{pK}_{\mathrm{a}}$ values $(4.18,5.41)$, only $\mathrm{pK}_{2}$ is significant at this pH . The amount of free phthalic acid $\left(\mathrm{PH}_{2}\right)$ will be negligible. Thus, only one Henderson-Hasselbalch equation is necessary to describe the solution equilibrium

$$
5.75=5.41+\log \frac{\mathrm{P}^{2-}}{\mathrm{PH}^{1-}}
$$

For material balance, the equation for osmolarity can be used, while the value for $\mathrm{K}^{+}$is obtained from the ionic balance equation

$$
\mathrm{M}_{\mathrm{os}}=\mathrm{PH}^{1-}+\mathrm{P}^{2-}+\mathrm{K}^{+} \quad \mathrm{K}^{+}=\mathrm{PH}^{1-}+2 \mathrm{P}^{2-} .
$$

Substituting and solving gives

$$
\begin{aligned}
\mathrm{PH}^{1-} & =0.016 \mathrm{M} \\
\mathrm{c}_{\mathrm{t}} & =0.05 \mathrm{M}
\end{aligned} \mathrm{P}^{2-}=0.034 \mathrm{M}, ~ \mathrm{~K}^{+}=0.084 \mathrm{M}
$$

Example 9: Calculate the True $\mathbf{p H}$, Given the Thermodynamic $\mathbf{p K}$ and Composition by Using an Activity Coefficient Correction
9. What will be the actual pH , at $25^{\circ}$, of a 0.1 M TRIS-chloride buffer in which the molarity of the free base ( $\mathrm{TH}^{+}$) is 0.0333 , that of the positive ion ( T ) 0.0667 ?

The Henderson-Hasselbalch equation is

$$
\mathrm{pH}=8.06+\log \frac{\mathrm{T}}{\gamma \mathrm{TH}^{+}}
$$

In order to find $\gamma$, first calculate the ionic strength

$$
\begin{gathered}
\mathrm{I}=\frac{1}{2}\left(\mathrm{TH}^{+} \times 1+\mathrm{Cl}^{-} \times 1\right)=\mathrm{TH}^{+}=0.0667 \\
\sqrt{\mathrm{I}} \quad=0.258
\end{gathered}
$$

Then, calculate the activity coefficient

$$
\begin{aligned}
& -\log \gamma=\frac{A z^{2} \sqrt{\mathrm{I}}}{1+\sqrt{\mathrm{I}}}-0.1 \mathrm{z}^{2} \mathrm{I} \\
& -\log \gamma
\end{aligned} \begin{aligned}
& =\frac{0.512 \times 1 \times 0.258}{1+0.258}-0.1 \times 1^{2} \times 0.0667 \\
& =0.098 \\
\gamma & =0.798
\end{aligned}
$$

Solving the Henderson Hasselbalch equation with the values for $\mathrm{TH}^{+}$, T , and $\gamma$

$$
\begin{aligned}
& \mathrm{pH}=8.06+\log \frac{\mathrm{T}}{\gamma \mathrm{TH}^{+}} \\
& \mathrm{pH}=8.06+\log \frac{0.0667}{0.798 \times 0.0333}=7.86
\end{aligned}
$$

Without using the activity coefficient, the estimated pH value is

$$
\mathrm{pH}=8.06+\log \frac{0.0667}{0.0333}=7.76
$$

## Example 10: True Composition of a Buffer of Given pH and Molarity with Activity Coefficient Correction

10. Calculate the true composition of a 0.05 M potassium phthalate buffer of pH 5.75 .

As noted in problem 8, the significant species are $\mathrm{PH}^{-}$and $\mathrm{P}^{2-}$. The Henderson-Hasselbalch equation, including activity coefficients is

$$
\begin{gathered}
5.75=5.41+\log \frac{\gamma_{2} \mathrm{P}^{2-}}{\gamma_{1} \mathrm{PH}^{1-}} \\
\mathrm{PH}^{-}+\mathrm{P}^{2-}=0.05
\end{gathered}
$$

Both $\gamma_{1}$ and $\gamma_{2}$ are dependent on the ionic strength, which is dependent on [ $\left.\mathrm{PH}^{-}\right]$and $\left[\mathrm{P}^{2-}\right]$. Since an analytic solution of this problem is difficult, an iterative approach will be used instead. First, calculate a first iteration composition, neglecting activity coefficients

$$
\begin{gathered}
\mathrm{P}_{1}+\mathrm{P}_{2}=0.05 \\
\mathrm{PH}^{-}=0.016 \mathrm{M} ; \quad \mathrm{P}^{2-}=0.034 \mathrm{M} \\
\mathrm{~K}^{+}=\mathrm{P}_{1}+2 \mathrm{P}_{2}=0.084 \mathrm{M}
\end{gathered}
$$

Next, calculate a first iteration ionic strength

$$
\begin{gathered}
\mathrm{I}=\frac{1}{2}\left(\mathrm{PH}^{-} \times 1+\mathrm{P}^{2-} \times 4+\mathrm{K}^{+} \times 1\right)=0.119 \\
\mathrm{I}^{1 / 2}=0.344
\end{gathered}
$$

Then, calculate first iteration values of $\gamma_{1}$ and $\gamma_{2}$

$$
\begin{gathered}
-\log \gamma_{1}=\frac{0.512 \times 1 \times 0.344}{1+0.344}-0.1 \times 1 \times 0.119 \\
-\log \gamma_{2}=\frac{0.512 \times 4 \times 0.344}{1+0.344}-0.1 \times 4 \times 0.119 \\
\gamma_{1}=0.760 ; \quad \gamma_{2}=0.333 .
\end{gathered}
$$

Now, calculate a second iteration composition, using the estimates for the composition and activity coefficients obtained from the first iteration

$$
\begin{array}{cc}
5.75=5.41+\log \frac{0.333 \mathrm{P}^{2-}}{0.760 \mathrm{PH}^{1-}} \\
& \mathrm{P}_{1}+\mathrm{P}_{2}=0.05 \\
\mathrm{PH}^{1-}=0.00834 & \mathrm{P}^{2-}=0.0417
\end{array}
$$

From these values, calculate second iteration values for the ionic strength, and the activity coefficients $\gamma_{1}$ and $\gamma_{2}$. Proceeding as above, $\gamma_{1}=0.752$ and $\gamma_{2}=0.320$ are obtained. Now, calculate the composition in a third iteration

$$
\begin{gathered}
5.75=5.41+\log \frac{0.320 \mathrm{P}^{2-}}{0.752 \mathrm{PH}^{1-}} \\
\mathrm{P}_{1}+\mathrm{P}_{2}=0.05 \\
\mathrm{PH}^{1-}=0.00814
\end{gathered} \quad \mathrm{P}^{2-}=0.0419 \quad \mathrm{~K}^{+}=0.0919 \quad 9
$$

These third iteration values differ from the second iteration values by only 2 parts in 10,000, and hence these values closely represent the true composition. Another round of iteration would not change these values substantially. Note, in this case, that the error in the composition estimated without activity coefficients is substantial. The osmolarity would be 0.142 , not 0.134 , as assumed in example 8.

## Example 11: Change of $\mathbf{p H}$ on Dilution

11. Calculate the $\mathbf{p H}$ of the buffer described in example 10 after 5 -fold dilution to 0.01 M.

In this situation, the composition of the buffer would normally be known, so the calculation is straightforward. The composition after dilution is:

$$
\mathrm{PH}^{1-}=0.00163 \quad \mathrm{P}^{2-}=0.00838 \quad \mathrm{~K}^{+}=0.0184
$$

The ionic strength is:

$$
\begin{gathered}
\mathrm{I}=\frac{1}{2}\left(\mathrm{PH}^{1-} \times 1+\mathrm{P}^{2-} \times 4+\mathrm{K}^{+} \times 1\right)=0.0268 \\
\sqrt{\mathrm{I}}=0.164
\end{gathered}
$$

The calculated activity coefficients are

$$
\gamma_{1}=0.852 \gamma_{2}=0.527
$$

The Henderson-Hasselbalch equation is

$$
\begin{aligned}
\mathrm{pH} & =\mathrm{pK}+\log \frac{\gamma_{2} \mathrm{P}^{2-}}{\gamma_{1} \mathrm{PH}^{1-}} \\
& =5.41+\log \frac{0.527 \mathrm{P}^{2-}}{0.852 \mathrm{PH}^{1-}} \\
& =5.41+\log \frac{0.527 \times 0.00838}{0.852 \times 0.00163} \\
& =5.91
\end{aligned}
$$

The pH has increased by 0.16 unit.
